## **ABSTRACT**

Continuous water-level data collected from 53 wells in South Carolina during 1990 provide the basic data for this report. Hydrographs are presented for selected wells to illustrate the effects that changes in ground-water recharge and artificial ground-water discharge have had on the ground-water reservoirs in the State. Daily mean water levels are listed in tables. Monthly mean water levels for 1990 and for the entire period of record at each monitoring well are depicted in hydrographs. Also included are precipitation records from ten National Weather Service stations in South Carolina.

## **INTRODUCTION**

Monitoring water levels is essential to the management of a ground-water reservoir or aquifer. Fluctuations and long-term trends in ground-water levels occur as a result of natural or artificial changes in recharge to and discharge from the aquifer. The amount of recharge to an aquifer varies in response to precipitation, evapotranspiration from the unsaturated zone, and surface-water infiltration. Discharge occurs as natural flow from an aquifer to streams, springs, lakes, and the ocean, as evapotranspiration from plants rooted in the saturated zone, and as withdrawals from wells.

This report, prepared by the U.S. Geological Survey (USGS) in cooperation with the South Carolina Department of Natural Resources-Water Resources Division, presents ground-water level data for major aquifers in South Carolina. Hydrographs from 53 wells were selected to illustrate the effects that changes in ground-water recharge and discharge have had on the water levels of various aquifers in the State. Hydrographs show monthly mean water levels for 1990 and for the entire period of record at each site. Precipitation graphs selected from ten weather stations in South Carolina show annual and cumulative trends. Ground-water level fluctuations due to precipitation are evident in many of the selected wells.

## MAJOR AQUIFERS

Different geologic features and geomorphic landforms of the three distinct physiographic provinces in South Carolina cause ground-water conditions in one part of the State to differ from those in another (fig. 1). The most productive aquifers (highest yields) in South Carolina are in the Coastal Plain Province, which includes the southeastern two-thirds of the State. The Coastal Plain is underlain by relatively continuous layers of sand, clay, and some limestone that dip and thicken to the southeast. In the Coastal Plain, aquifers are generally confined, except for the shallow surficial aquifer and for the outcrop areas of the major aquifers near the Fall Line. Major aquifers of the Coastal Plain in South Carolina, from youngest to oldest, include the predominantly limestone Floridan aquifer and its clastic equivalent, the Tertiary sand aquifer, the Black Creek aquifer, the Middendorf aquifer, and the Cape Fear aquifer. The Piedmont and Blue Ridge Provinces in the northwestern one-third of South Carolina are underlain by massive igneous and metamorphic rocks that form aquifers of low to unknown permeability. Names used to designate the aquifers have been adopted from common usage and are synonymous for the most part with the names of geologic formations that contain the principal water-bearing materials (fig. 2). The major aquifers are described in figure 2.

### Coastal Plain Aquifers

The sediments of the Coastal Plain Province thicken from the Fall Line toward the coast and consist of layers of sand, silt, clay, and some limestones of Late Cretaceous to Holocene age. These sediments are deposited on pre-Cretaceous, consolidated rocks. The province can be divided into aquifers and confining units on the basis of relative permeabilities, areal extent, and lithologic continuity of the sediments. The aquifers consist of sand, silty sand, or highly permeable limestone. Water generally moves laterally within each of the aquifers from areas of high head (water level) to areas of low head. The confining units consist of clay, silt, or low-permeability limestone that inhibit but do not prevent the vertical movement of ground water between aquifers. The more permeable aquifers are able to store and transmit large quantities of water and are important sources of water for municipal, industrial, and agricultural uses.

A major source of ground-water recharge to the Coastal Plain aquifers is rainfall in areas where the aquifers crop out at land surface or subcrop beneath a thin veneer of permeable surface material. Rainfall percolates vertically downward through the unsaturated zone to the aquifer, and then flows laterally through the aquifer down the hydraulic gradient, generally toward the southeast. Most of the natural discharge from the aquifers occurs in the upper Coastal Plain into streams and rivers incised into the aquifer. In the lower Coastal Plain, natural discharge from aquifers is upward to the surficial sediments, streams, or the ocean.

### **Surficial Aquifer**

The surficial aquifer is a water-table aquifer and is present throughout the Coastal Plain. Water-table conditions also occur in the Tertiary sand, Black Creek, and Middendorf aquifers where they crop out in the upper Coastal Plain. In general, the surficial aquifer consists of deposits that range in age from Late Cretaceous to Holocene and are less than 100 ft thick. It contains water under unconfined conditions, although semiconfined conditions may be present locally. This aquifer is used primarily for domestic and other low-yield supplies, but, in some areas, such as North Myrtle Beach where beds of coquina are present, yields can approach hundreds of gallons per minute (Speiran and Lichtler, 1986) (table 1).

Water-level fluctuations, as observed in wells screened in these aquifers, are caused mainly by changes in precipitation. Water levels generally rise rapidly during wet periods and decline slowly during dry periods. During prolonged droughts, well failures may occur, particularly on steep slopes when water levels decline below pump intakes in dug, bored, or shallow drilled wells. Generally, the well yields are restored with the return of precipitation.

### **Floridan Aquifer**

The Floridan aquifer is generally known in South Carolina as the Tertiary limestone aquifer and in Beaufort and Jasper Counties as the principal artesian aquifer. The principal water-bearing units are the Santee and Ocala Formations of Eocene age. These formations consist of creamy-yellow to white, fossiliferous limestone. Typically, the upper part of each unit, particularly the Ocala limestone, contains extensive loosely cemented shell deposits. These limestones are the facies equivalents of the Eocene sands of the Tertiary sand aquifer. The Floridan aquifer extends laterally over a triangular-shaped section of southern South Carolina.

In aquifer outcrop areas, water levels in wells tapping the Floridan aquifer fluctuate seasonally in response to ground-water recharge from precipitation. Where the aquifer is deeply buried, (greater than 100 ft) ground-water levels respond primarily to withdrawals, and the fluctuations caused by recharge are less pronounced. Near the coast, ground-water levels also respond to tidal changes in nearby saltwater bodies.

### **Tertiary Sand Aquifer**

The Tertiary sand aquifer can be divided into two units. The upper unit is the updip sand facies equivalent of the downdip limestone facies of the Floridan aquifer, and extends laterally from near the Fall Line to the sand-limestone facies interface with the Floridan aquifer. Sediments composing the upper unit include the Barnwell, McBean, and Congaree Formations. They range in age from Early to Late Eocene and consist of a continuous red, gray, greenish-yellow, fine to coarse-grained sand, with layers and lenses of gray to green clay and greenish marl (Siple, 1959). Marl is particularly notable in the McBean Formation.

The lower unit of the Tertiary sand aquifer extends laterally to the south from its outcrop in the north-central part of the Coastal Plain. This unit underlies part of the upper Tertiary sand aquifer and all of the Floridan aquifer. The lower unit of the aquifer consists of sediments of early Eocene and Paleocene age, including the more permeable upper Black Mingo Formation.

Sediments from these Tertiary sand formations are grouped together and called the Tertiary sand aquifer, because, on a regional basis, they act as a single aquifer. The Tertiary sand aquifer and the Floridan aquifer can be treated as a single hydrologic unit in South Carolina, because there are no significant water-level differences between them and no evidence of an intervening confining unit (Aucott and Speiran, 1985b).

## **Black Creek Aquifer**

The Black Creek aquifer, of Late Cretaceous age, ranges in thickness from a few feet in updip outcrop areas to about 800 ft in coastal areas. This aquifer consists primarily of the permeable sediments of the Black Creek Formation but may contain sediments of overlying formations or the underlying Middendorf Formation. The Black Creek is the uppermost regional aquifer and consists of thinly laminated (and interbedded) sand and clay lenses. The updip limit of the Black Creek aquifer is located in the upper Coastal Plain and is generally parallel to the Fall Line. The aquifer crops out in the eastern part of the Coastal Plain, and is present in the subsurface throughout most of the Coastal Plain of South Carolina.

## **Middendorf Aquifer**

The Middendorf aquifer, of Late Cretaceous age, consists mostly of sediments of the Middendorf Formation (and their stratigraphic equivalents) but may include sediments of the overlying Black Creek Formation or the underlying Cape Fear Formation. This unit also has been referred to as the Tuscaloosa Formation (Cooke, 1936).

In outcrop areas and beneath the upper Coastal Plain, sediments of the Middendorf aquifer are primarily light gray, white to buff sand frequently interfingered with lenses of white, pink, or purple clay. In the lower Coastal Plain, the sediments of the Middendorf aquifer are lithologically similar to those of the Black Creek aquifer. The Middendorf aquifer exists throughout the Coastal Plain of South Carolina and crops out along most of the length of the Fall Line. The aquifer generally thickens from the Fall Line toward the coast.

## **Cape Fear Aquifer**

The Cape Fear aquifer is the basal aquifer in the Coastal Plain aquifer system of South Carolina. In most areas it consists of sand, silt, and gravel separated by relatively thick silt and clay layers. This unit has not been well defined in the Coastal Plain of South Carolina, but it probably occurs only in the lower Coastal Plain and in the eastern part of the upper Coastal Plain. The Cape Fear aquifer is not known to crop out in South Carolina. The extent of the Cape Fear aquifer is not well defined because it is rarely penetrated by wells, it is deeper and generally is less productive than the overlying Middendorf aquifer, and the aquifer contains high concentrations of dissolved solids in the lower Coastal Plain.

## **Piedmont and Blue Ridge Aquifers**

The igneous and metamorphic rocks in the Piedmont and Blue Ridge Provinces have little primary porosity or permeability, and individual aquifers are not areally extensive. Ground-water storage and movement occurs in unconsolidated material (alluvium and saprolite) overlying the crystalline rock, and in joints, fractures, and other types of secondary porosity within the rock. The largest yields are from wells constructed in the alluvium and saprolite overlying the unweathered bedrock. The quality and quantity of water generally is suitable for domestic uses.

Ground-water levels in the crystalline rock aquifers are affected mainly by precipitation and evapotranspiration. Ground-water levels rise rapidly with the onset of late-winter rains and reduced evapotranspiration, and generally reach their highest levels for the year in March or April. Increases in evapotranspiration and decreases in rainfall during the spring and early summer cause ground-water levels to decline. Heavy precipitation in midsummer may cause small rises in ground-water levels, but the lack of recharge from light rainfall in the autumn results in water levels declining to the annual lows, usually in October or November.

## PRECIPITATION DATA

Precipitation is one of the principle sources of ground-water recharge to aquifers. Monthly mean precipitation data furnished by the National Oceanic and Atmospheric Administration (NOAA) are shown for ten precipitation stations. Locations of the precipitation stations are shown in figure 3. Monthly precipitation was compared to the 30-year (1951-80) average for each station (figs. 4-13 at end of report). The upper graph on each figure shows the monthly departure from normal and cumulative departures from normal for 1990. The lower graph shows the cumulative departure from normal precipitation for 1981-90.

Precipitation was below normal over most of South Carolina for 1990. Only two of the stations, Clemson and Chester, had annual departures above normal; 1.40 in. and 0.63 in., respectively. The other eight stations had annual departures below normal ranging from -0.60 in. at Kingstree to -9.68 in. at Beaufort.

For 10 years (1981-90), the cumulative departure of precipitation was below normal at 9 of the 10 stations. Only the Aiken station showed a cumulative departure of precipitation above normal.

## GROUND-WATER DATA

Water levels were continuously monitored in 53 wells located in the surficial, Floridan, Tertiary sand, Black Creek, Middendorf, Cape Fear, and Piedmont and Blue Ridge aquifers. The locations of monitoring wells are shown in figure 14 (at end of report). The locations of wells in each aquifer are listed in table 2 and shown in figures 15 to 21 (at end of report). For each well, daily mean water levels are listed in tables 3 to 55 (at end of report) and hydrographs are shown in figures 22 to 74 (at end of report). The monthly mean water levels for the period of record for each well are also shown in hydrograph form. In cases of missing data, monthly mean water levels were determined where there were five or fewer missing days. In this report, the annual hydrographs are plotted from daily mean values; therefore, a record low or record high water level that occurred on a particular day would have been higher or lower than that shown on the hydrograph. Similarly, the period-of-record hydrographs are plotted from monthly mean values; therefore, a record low or a record high instantaneous or daily value that occurred on a particular day would have been higher or lower than that shown on the hydrograph.

Water-level fluctuations due to precipitation are evident in many of the USGS network wells. Thirty-nine of the 53 wells in this report showed noticeable increases in water levels after October 10 - 11, 1990, when heavy rain from tropical storms Klaus and Marco fell statewide. For example, the Florence Airport reported rainfall of 4.35 in. and 3.47 in. on October 10 and 11, respectively, and the water level at well FLO-85 increased 2.91 ft from October 9 to October 12, 1990.

It is difficult to use any particular well as an indicator of the relative fluctuation of the water-level (or potentiometric surface) within an aquifer, because changes in water levels in a well may be attributed to a specific, localized phenomena rather than a generalized aquifer response. Many of the water levels in the Floridan aquifer were slightly lower in 1990 as compared to 1989. Water levels in the Black Creek aquifer also showed a general decline during the year. While the water levels in well GEO-77 decreased 5.25 ft (from 97.99 ft to 103.24 ft below land surface) and in HO-307 decreased 2.73 ft (from 59.50 ft to 62.23 ft below land surface), water levels in GEO-84 increased 5.81 ft (101.05 ft to 95.24 ft below land surface). Many of the wells in the Middendorf aquifer showed a slight decrease in water levels (less than 0.5 ft) over the year with the notable exception of BRK-431, which showed a decline of 6.16 ft (2.55 ft to 8.71 ft). Two of the wells in the Piedmont aquifer, GRV-709 and YK-147, showed a water-level rise of 0.98 ft and 1.16 ft, respectively, whereas RIC-309, also in the Piedmont aquifer, showed a decline of 4.09 ft.
